Conclusion

Why Long-Lived-Particles (LLPs)?

Motivation for LLP

LLPs?

- LLPs ($\tau \sim \text{ns}, c\tau \sim \text{cm}$) : essential part of SM \Rightarrow Reason to believe for them to be in BSM

Dark-matter as LLPs?

- Models of WIMP DM \rightarrow Null results to date in indirect detection (ID), direct detection (DD), and missing energy searches
 - WIMP DM \rightarrow Severely constrained regions of parameter space
 - Broader investigation into possible signals of particle dark matter

Conclusion

Lifetime of a particle

Decay rates

- Large collection : *decaying particles* at time t : $N(t)$.
- Decay rate Γ : *probability per unit time* \rightarrow given particle disintegrate
- Rate : particles *decrease*

$$\frac{dN}{dt} = -\Gamma N \Rightarrow N(t) = N(0) e^{-\Gamma t}$$

- Mean lifetime \rightarrow reciprocal of the decay rate

$$\tau = \frac{1}{\Gamma}$$

- Reality : most particles \rightarrow decay by several different routes.
 - *Total decay rate* \rightarrow sum of individual rates and so is their *lifetimes*

$$\Gamma_{\text{tot}} = \sum_{k=1}^n \Gamma_k \Rightarrow \tau = \frac{1}{\Gamma_{\text{tot}}}$$

- Branching ratios for k 'th decay mode : $\frac{\Gamma_k}{\Gamma_{\text{tot}}}$

Parameters that make particles Long Lived

$$\Gamma_f = 2\pi \underbrace{|T_f|^2}_{\propto \alpha} \underbrace{\rho(E_f)}_{\sim \text{mass}}$$

$$\tau = (\sum \Gamma_f)^{-1}$$

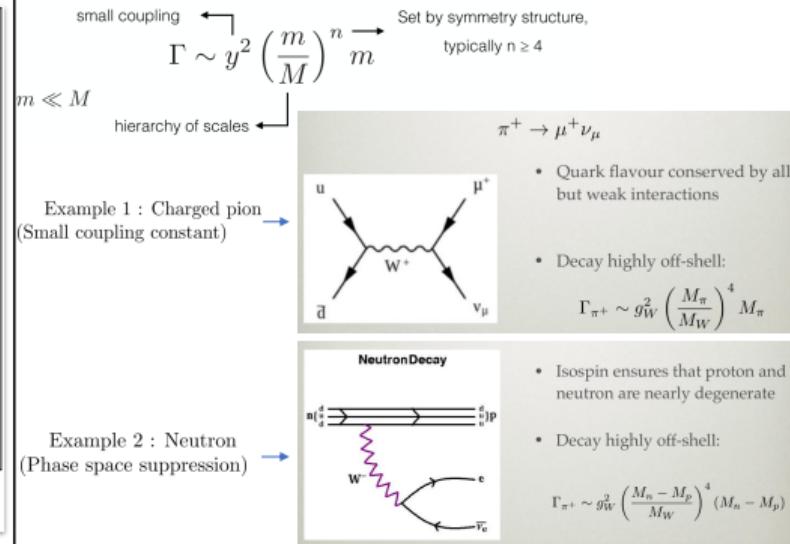

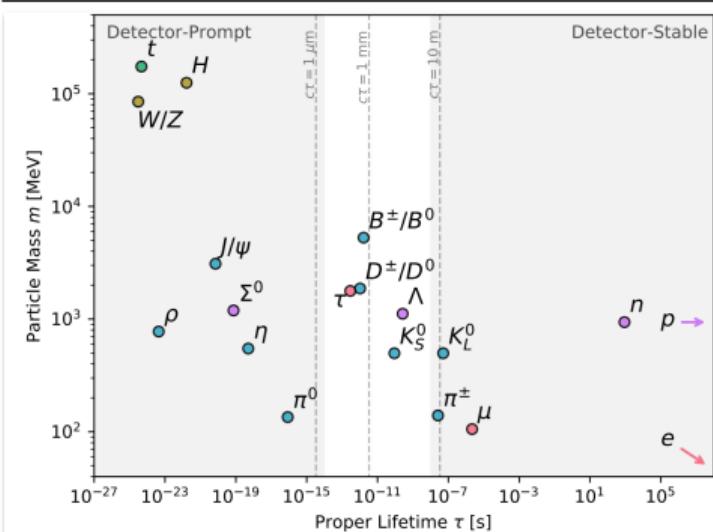

Coupling constant

Density of states

Scale suppression

- Particle decay rate : strong force > electromagnetic or weak

- Symmetries : Small DOS → a longer lifetime
- General trend : High mass particles → smaller lifetimes
- Decay : suppressed by scale of the physical system mediating decay

Multiple DM theories predicting LLPs

		Small coupling	Small phase space	Scale suppression
SUSY	GMSB			✓
	AMSB		✓	
	Split-SUSY			✓
	RPV	✓		
NN	Twin Higgs	✓		
	Quirky Little Higgs	✓

DM	Freeze-in	✓		
	Asymmetric			✓
	Co-annihilation		✓	
Portals	Singlet Scalars	✓		
	ALPs			✓
	Dark Photons	✓		
	Heavy Neutrinos			✓

Figure: Table of theories predicting LLPs[1]

Freeze-in DM (FIMPs)

- Decay responsible → DM accumulation

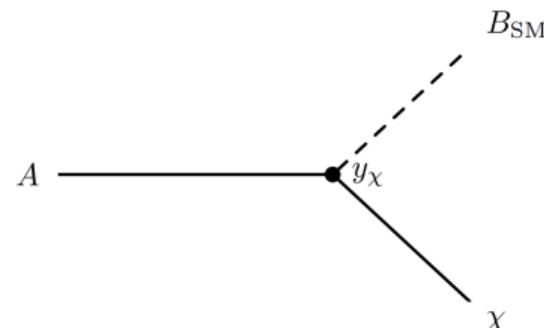

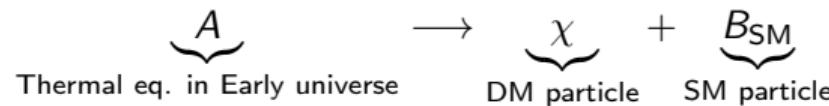

Figure: Toy diagram of a freeze-in scenario

- Feeble coupling constant y_χ → Making χ thermally decoupled from the plasma
- This *feebleness* ⇒ **long lifetime** of A

Freeze-in DM : Decay rate

- **Relic abundance** of χ is related to the A decay width Γ_A by

$$\underbrace{\Omega_\chi h^2}_{\text{Cosmo. den. of } \chi} = \frac{10^{27}}{g_*^{\frac{3}{2}}} \frac{m_1 \Gamma_A}{m_2^2}$$

g_* is the number of relativistic degrees of freedom at temperatures $T \approx m_2$ (around the A mass)

- In the SM $g_*(100 \text{ GeV}) \simeq 100$ and $g_*(100 \text{ MeV}) \simeq 10$
- Assuming $\chi \rightarrow$ all DM today i.e. $\Omega_\chi h^2 = 0.11 \rightarrow$ inverse decay width of A as

$$\Gamma^{-1}(A \rightarrow \chi + B_{\text{SM}}) \sim \left(\frac{m_1}{100 \text{ GeV}} \right) \left(\frac{200 \text{ GeV}}{m_2} \right)^2 \left(\frac{100}{g_*(m_2)} \right)^{3/2} \times 10^6 \text{ ns} \sim 0.01 \text{ secs}$$

Co-annihilating DM

- **DM relic abundance** → *annihilation between two different species*
- f : SM particle, ψ : BSM LLP, χ : DM particle
- Long lifetime → set by a *suppressed phase space*

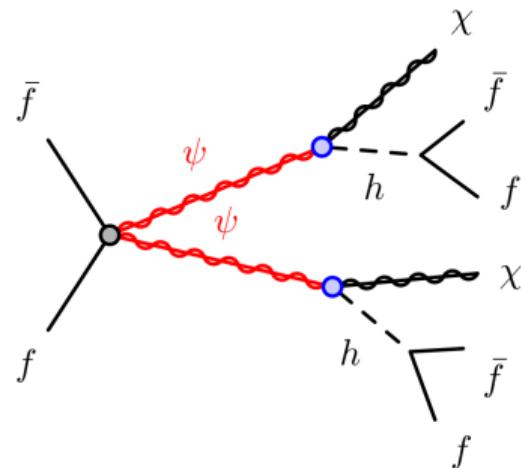

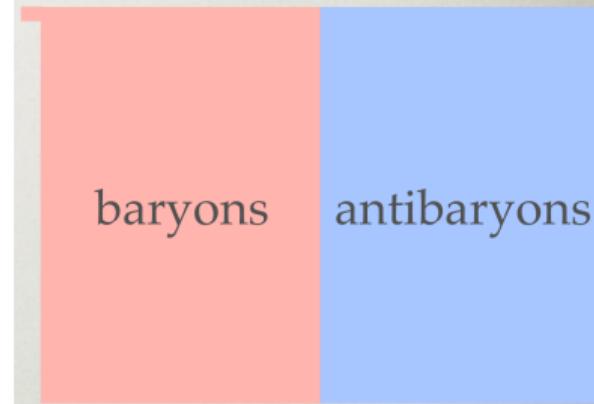

Figure: Feynman diagram for a co-annihilation scenario[1]

Asymmetric DM

- DM particle \neq own antiparticle : relic dark matter density \rightarrow particle-antiparticle asymmetry (Like the Baryon asymmetry)
 - DM production \rightarrow non-thermally (out-of-equilibrium process)
- Easiest scenario for DM production using asymmetry
 - Early universe : Particle species $\psi \rightarrow m_\psi > m_\chi$ with an abundance $\Omega_\psi \rightarrow$ decays to χ

$$\Omega_\chi \simeq \Omega_\psi \frac{m_\chi}{m_\psi}$$

Conclusion

Detecting Dark-matter

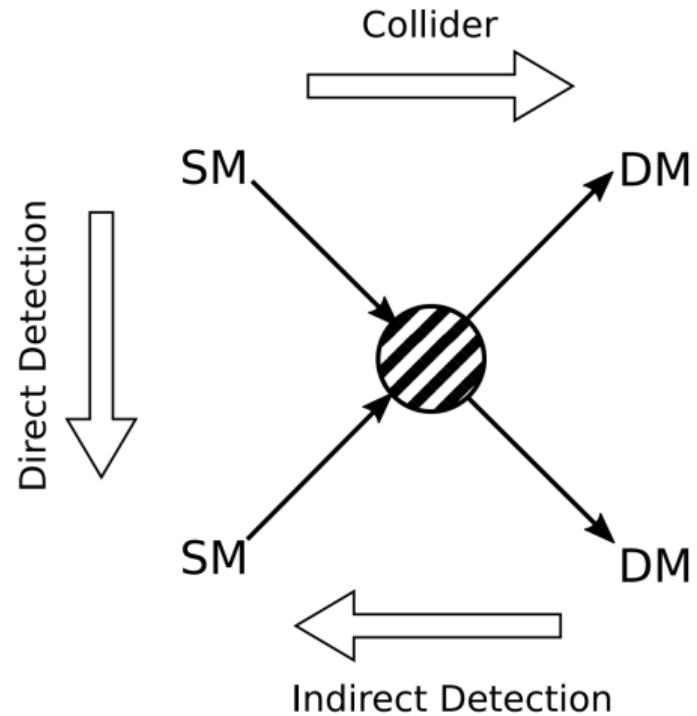

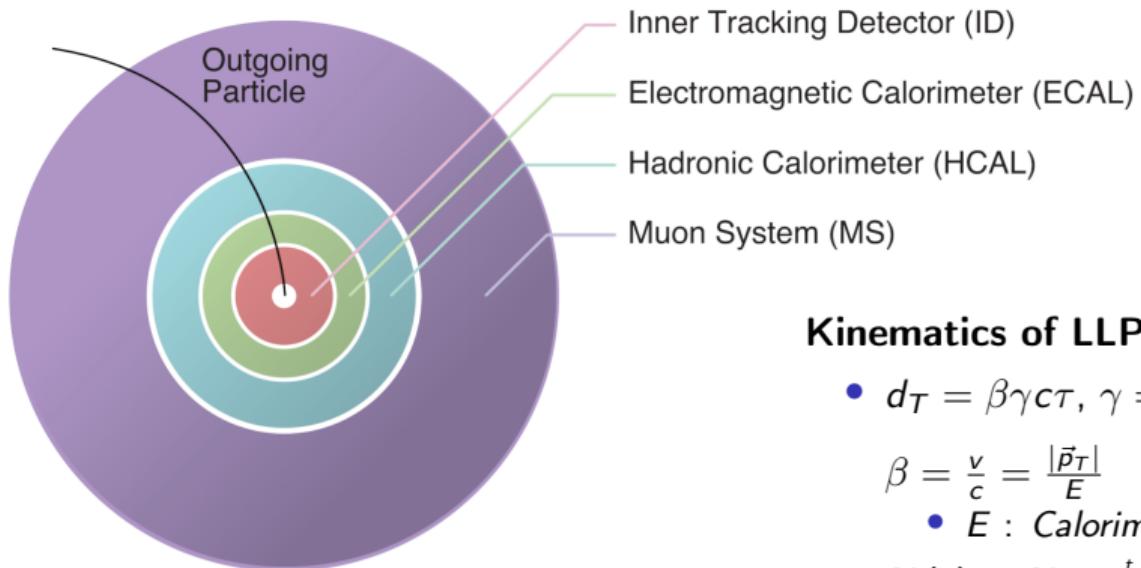

Figure: [3]

Kinematics in a detector

Kinematics of LLPs [1]

- $d_T = \beta\gamma c\tau$, $\gamma = \frac{E}{m} = \frac{1}{\sqrt{1-\beta^2}}$,
- $\beta = \frac{v}{c} = \frac{|\vec{p}_T|}{E}$
- E : Calorimeter, $|\vec{p}_T|$: Track bend
- $N(t) = N_0 e^{-\frac{t}{\tau}}$
- $P_{\text{dec}} = \frac{1}{4\pi} \int_{\Delta\Omega} d\Omega \int_{L_1}^{L_2} \frac{1}{d} e^{-\frac{L}{d}}$

Figure: Not to scale transverse schematic of a typical collider [1]

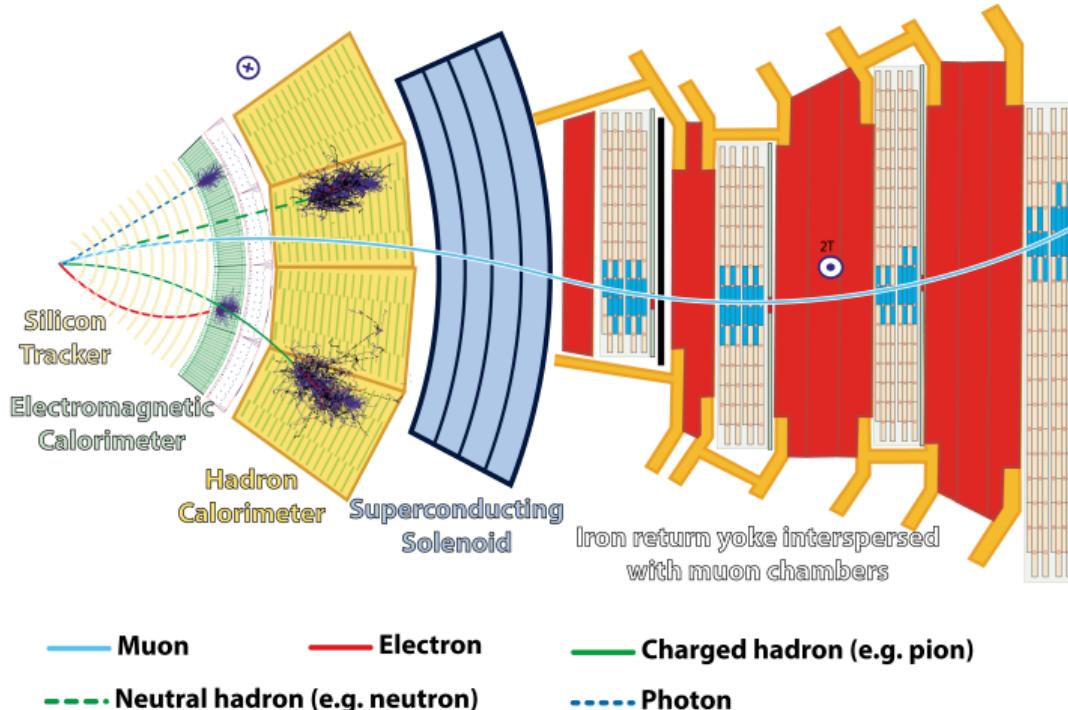

Figure: Cross section of a collider[4]

- Particles produce → region of ionization → solid-state / gaseous detectors → *hits*.
 - Fit into trajectory → *track* → Get charge / momentum

Decays within the tracker

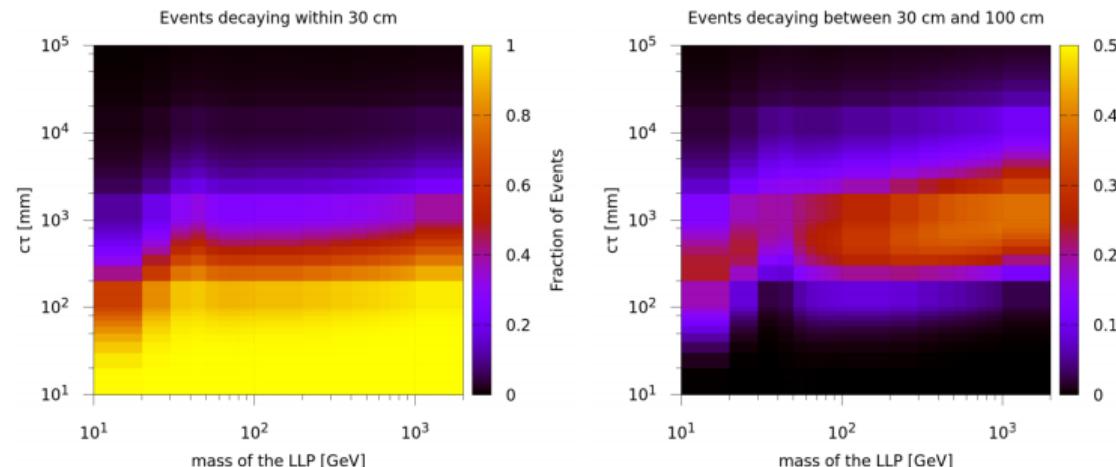

Figure: Fraction of LLPs decaying → Left : within 30 cm, Right : between 30 - 100 cm [2]

- Most theories : Predict lifetimes of LLP $\gg 25$ ns.
- Detect them in conventional subsystems due to \rightarrow Exponential decay probability

Direct detection : Anomalous Ionization

- CLLP → Leaves *track* in ID ⇒ Direct detection possible
 - If $m_{\text{CLLP}} > m_{\text{proton}}$ → Produced with lower β (Compared to : Track forming SM particle)
 - Detect : Slow moving / heavily charged particle → Anomalously large $\langle \frac{dE}{dx} \rangle$
 - Bethe-Bloch formula $\langle \frac{dE}{dx} \rangle \sim -\frac{z^2}{\beta^2} \cdot \left[\ln\left(\frac{\beta^2}{(1-\beta^2)}\right) - \beta^2 + C \right]$ (Ionization energy lost per unit distance traveled)

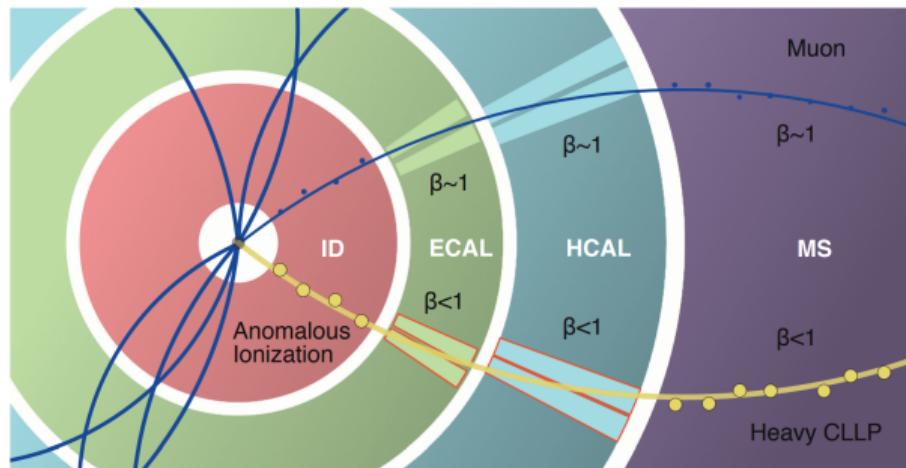

Figure: Anomalous ionization of a heavy CLLP[1]

Indirect detection I : Displaced Tracks

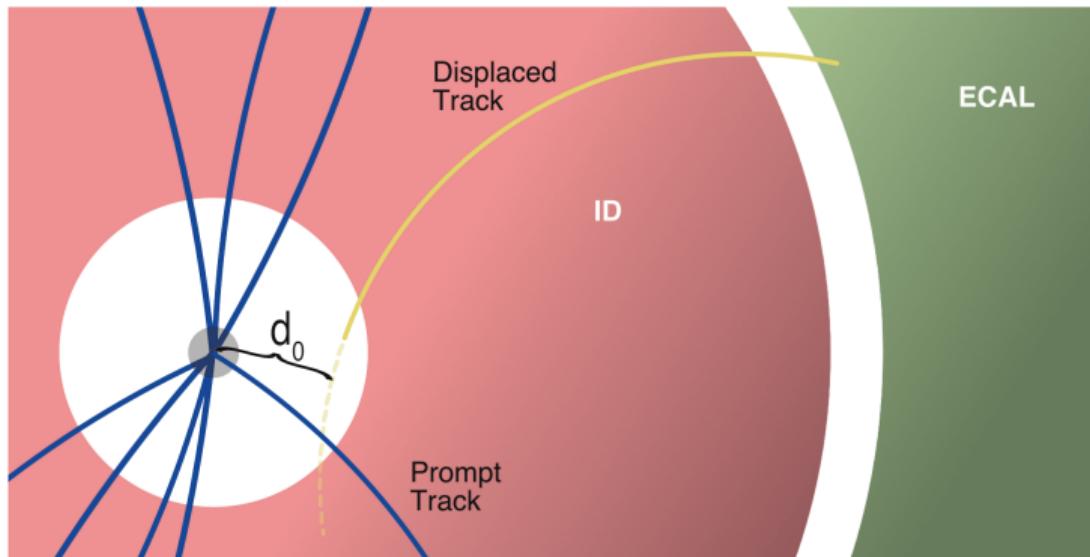

Figure: Displaced track vs Prompt track[1]

- Neutral LLP \rightarrow Transverses some macroscopic distance within ID
 - Decays into charged particle/s \rightarrow Leaves a *displaced track* or a *displaced vertex* (next slide)

Conclusion

LLP specific detectors

FASER

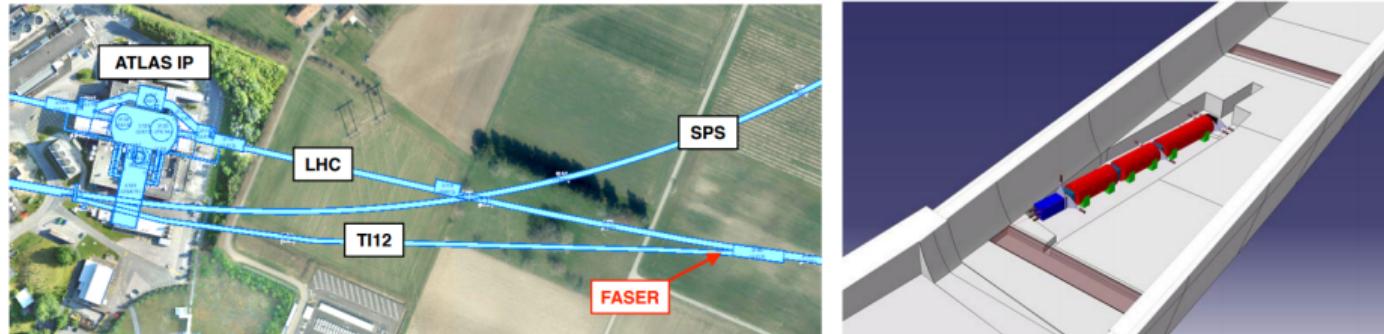

Figure: Left : Location of FASER w.r.t Atlas, Right : View of FASER in a tunnel[7]

- Goal : Detect LLPs / decay products → Transversed $\sim 150m$ (Inagurated May 2021)
- Isolation → Low SM background (Most SM background : near the ATLAS IP)
- New resolution/parameter space → LLP detection.

MATHUSLA

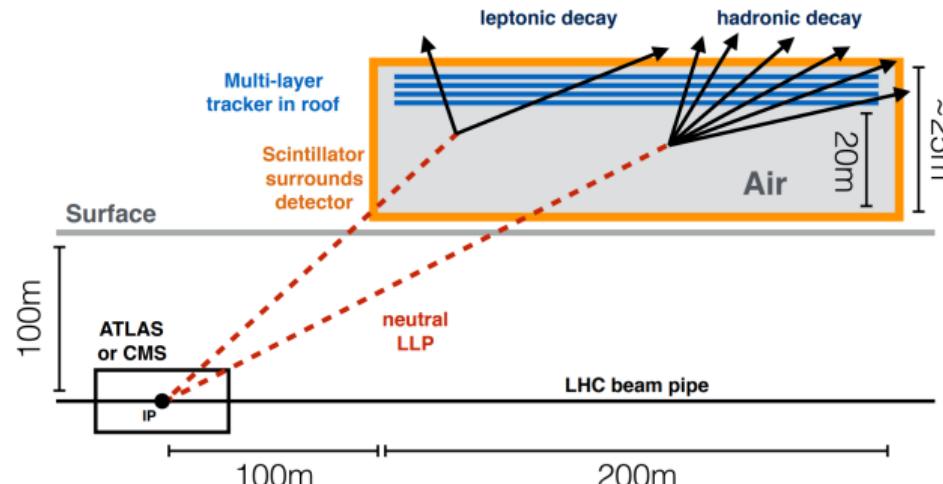

Figure: Schematic of proposed MATHUSLA detector[9]

- $200 \times 200 \times 20 \text{ m}^3$ in size, roughly 100 m above CMS/ATLAS caverns.
- Neutral LLPs : very large lifetimes produced in the collisions \rightarrow decay within the volume of MATHUSLA \rightarrow displaced vertices could be reconstructed

Conclusion

Figure: [10]

Conclusion

- LLPs → Natural prediction by many theories.
 - LLP searches important : It is a *strong DM candidate*, also to cover entire *spectrum of DM candidates*
- Increase chances of LLP detection,
 - *Low SM backgrounds*
 - Extra detectors : *far-distance* from collision point → *decay products* get an opportunity to be detected
- Very young field : huge potential for discovering different aspects of BSM, both theoretically and experimentally
